

Determinacy and Classification of Markov-Switching Rational Expectations Models: A Technical Guide

Seonghoon Cho*

October 14, 2023

Abstract

This is a technical guide for the *MOD* (minimum of modulus) method proposed by Cho (2021) in the class of general linear rational expectations (LRE) models and Markov-switching rational expectations (MSRE) models. This document provides a compact summary of the paper and illustrates how to implement the methodology. Current versions of the codes accompanying this technical guide and the numerical examples including the ones in the paper can be found at <https://sites.google.com/site/sc719en/research>. This technical guide and the matlab codes will be updated in the future.

*School of Economics, Yonsei University, 50 Yonsei-ro, Seodaemun-gu, Seoul, 120-749, Korea. *E-mail:* sc719@yonsei.ac.kr. Tel:+82-2-2123-2470; Fax:+82-2-393-1158

1 Introduction

This document explains how to implement the *MOD*(minimum of modulus) method of Cho (2021) using matlab for LRE and MSRE models. The proposed method uses only the most mean-square stable *MOD* solution for a complete classification of models into three mutually disjoint and exhaustive subsets: determinacy, indeterminacy and the case of no stable solution. A solution methodology for the *MOD* solution is also provided. The previous technical guide for Cho (2016) is modified and nested in this note.

2 MOD Method for LRE Models

2.1 LRE Models and RE solutions

$$x_t = AE_t[x_{t+1}] + Bx_{t-1} + Cz_t, \quad (1a)$$

$$z_t = Rz_{t-1} + \epsilon_t, \quad \epsilon_t \sim (0, D), \quad E_{t-1}\epsilon_t = 0_{m \times 1} \quad (1b)$$

x_t $n \times 1$ vector of endogenous variables,

z_t $m \times 1$ vector of mean-square stable exogenous variables,

ϵ_t $m \times 1$ vector of white noises,

A $n \times n$ coefficient matrix of the forward-looking endogenous variables,

B $n \times n$ coefficient matrix of the backward-looking endogenous variables,

C $n \times m$ coefficient matrix of the exogenous variables,

R $m \times m$ coefficient matrix of the lagged exogenous variables.

Writing a model into the form (1a): Any linear rational expectations model can be written as $B_1x_t = A_1E_t[x_{t+1}] + B_2x_{t-1} + C_1z_t$ where B_1, A_1, B_2 and C_1 by collecting the parameters of current, forward-looking, backward-looking endogenous variables and exogenous variables. Therefore, one can set $A = B_1^{-1}A_1$, $B = B_1^{-1}B_2$ and $C = B_1^{-1}C_1$.

Solution Forms, Restrictions and Full Set of MSV solutions

$$x_t = [\Omega x_{t-1} + \Gamma z_t] + w_t : \text{General RE solution}, \quad (2)$$

$$x_t = \Omega x_{t-1} + \Gamma z_t : (w_t = 0_{n \times 1}) : \text{MSV solution}, \quad (3)$$

$$w_t = FE_t w_{t+1} : (w_t \neq 0_{n \times 1}) : \text{Sunspot component}. \quad (4)$$

$$\Omega = (I_n - A\Omega)^{-1}B, \quad (5)$$

$$\Gamma = (I_n - A\Omega)^{-1}C + F\Gamma R, \quad (6)$$

$$F = (I_n - A\Omega)^{-1}A. \quad (7)$$

$$\mathcal{S} = \{\Omega_h \in \mathcal{C}^{n \times n} | \Omega_h \text{ solves (5), } \rho(\Omega_1) \leq \dots \leq \rho(\Omega_h) \leq \dots \leq \rho(\Omega_N)\} \quad (8)$$

where $\rho(M) = \max_{1 \leq i \leq n}(|\xi_i|)$, ξ_1, \dots, ξ_n are the eigenvalues of an $n \times n$ matrix M , and $N \leq \binom{2n}{n}$.

Definition 1 $x_t = \Omega_1 x_{t-1}$ is an MOD solution if $\rho(\Omega_1) = \min \rho(\Omega)$ for all $\Omega \in \mathcal{S}$.

2.2 The MOD Method

2.2.1 Classification of LRE Models by the MOD Method

The main classification result of the *MOD* method for LRE models is a special case of Proposition 3 of the paper.

Result 3 *Consider a LRE model (1) and the set of solutions \mathcal{S} in (8). Then, necessary and sufficient conditions for determinacy, indeterminacy and the case of no stable solution are given in Table (1). Moreover, if there exists a solution such that $\rho(\Omega)\rho(F) < 1$, it is the unique real-valued MOD solution and the model is determinacy-admissible.*

Table 1: **Classification of LRE Models by the MOD Method**

| | Determinacy-Admissible(DA): $\rho(\Omega_1)\rho(F_1) < 1$ | Determinacy-Inadmissible(DIA): $\rho(\Omega_1)\rho(F_1) \geq 1$ |
|--------------------|--|--|
| Determinacy | $\rho(\Omega_1) < 1, \rho(F_1) \leq 1$ | Impossible |
| Indeterminacy | $\rho(F_1) > 1$ | $\rho(\Omega^1) < 1$ |
| No Stable Solution | $\rho(\Omega_1) \geq 1$ | $\rho(\Omega^1) \geq 1$ |

2.2.2 Identification of the MOD Solution

The *MOD* methodology is completed by finding the *MOD* solution. In LRE models, identification of the *MOD* can be done by use of the eigensystem implied by the generalized Schur decomposition theorem. Such an identification is not possible for MSRE models because of the lack of an eigensystem. In principle, identification of the *MOD* can be done by solving all Ω , which is very difficult even for small-scale LRE models, let alone MSRE models. Partitioning the LRE models by Determinacy-Admissibility(DA) provide a crucial identification condition for the *MOD* solution. Implementation will be shown below.

2.3 Standard Methods Using Eigensystem

This section shows the equivalence between the *MOD* approach and the standard methods based on an eigensystem. This also helps understand our results in terms of well-known generalized eigenvalues. Let $y_t = [x'_t \ x'_{t-1}]'$. Model (1a) can be reformulated as

$$\tilde{B}y_t = \tilde{A}E_t y_{t+1} + \tilde{C}z_t \quad (9)$$

$$\tilde{B} = \begin{bmatrix} I_n & -B \\ I_n & 0_{n \times n} \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} A & 0_{n \times n} \\ 0_{n \times n} & I_n \end{bmatrix}, \quad \tilde{C} = \begin{bmatrix} C \\ 0_{n \times m} \end{bmatrix} \quad (10)$$

Let $\xi_{A,B}$ be the set of generalized eigenvalues implied by the model. Formally,

$$\xi_{A,B} = \{\xi_i \in \mathcal{C} | 0 = |\tilde{A} - \xi_i \tilde{B}|, |\xi_1| \leq |\xi_i| \leq |\xi_{2n}|\} \quad (11)$$

Any solution $\Omega \in \mathcal{S}$ is associated with n out of $2n$ eigenvalues. The corresponding F is associated with the inverses of the remaining n eigenvalues.

Using these properties, LRE models can also be classified as Table 2, which is exactly the same as Table 1, including the conditions for Determinacy-Admissibility(DA) and Determinacy-Inadmissibility(DIA). Detailed arguments for equivalence of the classification of LRE models using this standard eigensystem approach and the *MOD* method can be found in the paper.

Table 2: **Classification of LRE Models**

| | Determinacy-Admissible(DA): $\Omega(\xi_1, \dots, \xi_n) \in S$ and $ \xi_n < \xi_{n+1} $ | Determinacy-Inadmissible(DIA): $\Omega(\xi_1, \dots, \xi_n) \notin S$ or $ \xi_n = \xi_{n+1} $ |
|--------------------|---|--|
| Determinacy | $ \xi_n < 1 \leq \xi_{n+1} $ | Impossible |
| Indeterminacy | $ \xi_{n+1} < 1$ | $\rho(\Omega^1) = \xi_{n+i} < 1, i \geq 0$ |
| No Stable Solution | $ \xi_n \geq 1$ | $\rho(\Omega^1) = \xi_{n+i} \geq 1, i \geq 0$ |

Remark 1. Table 2 shows that a usual root-counting to identify determinacy can fail but only when $\Omega(\xi_1, \dots, \xi_n) \notin \mathcal{S}$. Therefore, the existence of the *MOD* solution must be checked along with root-counting, which is precisely what the *MOD* method does in line with the gensys algorithm of Sims (2002).

2.4 Implementing MOD Method for LRE Models

MOD method is to classify a given model into DET/INDET/NSS by identifying and computing the *MOD* solution. There are two main matlab codes for LRE models to be explain in the following section.

- **fmlre.m**: Implement the *MOD* method using the modified forward method.
- **qzmlre.m** Implement the *MOD* method using eigensystem.

There are two ways of implementing the method. First, QZ method does it all. This computes the *MOD* solution and checks whether $\Omega(\xi_1, \dots, \xi_n) \in \mathcal{S}$ using the eigensystem. Therefore, one can directly classify a given model using $\rho(\Omega_1)\rho(F_1)$ following Table 1. Second, a sequential way of first using the forward method and QZ method if necessary. The forward method computes the forward solution Ω^* . If this turns out to be the *MOD* solution, then classification is done. If it does not exist or if $\rho(\Omega^*)\rho(F^*) \geq 1$ and $\rho(\Omega^*) \geq 1$, the forward method cannot tell classification. Thus one needs to use an alternative technique to identify the *MOD* solution and complete classification. Here QZ method is suggested because the eigensystem directly yields the *MOD* solution. Note that in the MSRE models, QZ method is not available. Thus one must use a sequential approach of applying the forward method first and use the Gröbner basis approach if necessary. The sequential approach is not needed for LRE models, but it shows how it would work for MSRE models.

1. Implementing the *MOD* method using the QZ method.

- (a) Write your model in the form of (1a), e.g., “Ex.m”. Construct A. Construct B, C, or R if any.
- (b) Type and run **DETCMOD=qzmlre(A,B)**. Ω_1 is the *MOD* solution where $\text{DETCMOD}=[\rho(\Omega_1) \ \rho(F_1) \ \rho(\Omega_1)\rho(F_1)]$.
 - i. If $\rho(\Omega_1)\rho(F_1) < 1$, then the model is DA. $\rho(\Omega_1)$ and $\rho(F_1)$ tells whether the model is DET/INDET/NSS.
 - ii. If $\rho(\Omega_1)\rho(F_1) \geq 1$ and $\rho(\Omega_1) < 1$, the model is indeterminate. (The model is DIA)
 - iii. If $\rho(\Omega_1)\rho(F_1) \geq 1$ and $\rho(\Omega_1) \geq 1$, the model has no stable solution. (The model is DIA)

2. Implementing the *MOD* method using the forward method

(a) Same as above: 1.(a).

(b) Type and run $\text{DETC}=\text{fmlre}(\mathbf{A},\mathbf{B})$. Ω^* is the forward solution where

$$\text{DETC}=[\rho(\Omega^*) \ \rho(F^*) \ \rho(\Omega^*)\rho(F^*)].$$

- i. If $\rho(\Omega^*)\rho(F^*) < 1$, then $\Omega^* = \Omega_1$, and the model is DA. $\rho(\Omega_1)$ and $\rho(F_1)$ tells whether the model is DET/INDET/NSS. Done.
- ii. If $\rho(\Omega^*)\rho(F^*) \geq 1$ and $\rho(\Omega^*) < 1$, the model is indeterminate. No need to check whether $\Omega^* = \Omega_1$. Done.
- iii. If $\Omega^* = NaN$ (forward solution does not exist) or if $\rho(\Omega^*)\rho(F^*) \geq 1$ and $\rho(\Omega^*) \geq 1$, the forward method cannot tell the classification. Apply the alternative to find the *MOD* solution and complete classification.

Remark 1. Only the case i would arise in practice because cases ii and iii would arise for DIA models. Therefore, forward method would also be sufficient for classification of economic models.

Remark 2. In fact, forward method is even faster than standard methods in many cases.

3 MOD Method for MSRE Models

3.1 MSRE Models and RE solutions

The class of MSRE models:

$$x_t = E_t[A(s_t, s_{t+1})x_{t+1}] + B(s_t)x_{t-1} + C(s_t)z_t, \quad (12)$$

$$z_t = R(s_t)z_{t-1} + G(s_t)\epsilon_t, \quad \epsilon_t \sim (0, D) \quad (13)$$

ϵ_t is covariance-stationary, independent of s_{t-k} for all $k \geq 0$.

| | |
|----------------------|--|
| x_t | $n \times 1$ vector of endogenous variables, |
| z_t | $m \times 1$ vector of mean-square stable exogenous variables, |
| ϵ_t | $l \times 1$ vector of covariance-stationary processes independent of s_t , |
| s_t | S -regime ergodic Markov chain, |
| P | $S \times S$ transition matrix with $p_{ij} \equiv \Pr(s_t = j s_{t-1} = i)$, $i, j \in \{1, 2, \dots, S\}$, |
| $A(\cdot), B(\cdot)$ | $n \times n$ coefficient matrices, |
| $C(\cdot)$ | $n \times m$ coefficient matrix, |
| $R(\cdot)$ | $m \times m$ coefficient matrix. |
| $G(\cdot)$ | $m \times l$ coefficient matrix. |

Writing a model into the form (12): The original model would be written as $B_1(s_t)x_t = E_t[A_1(s_t, s_{t+1})x_{t+1}] + B_2(s_t)x_{t-1} + C_1(s_t)z_t$. Therefore, one can set $A(s_t, s_{t+1}) = B_1^{-1}(s_t)A_1(s_t, s_{t+1})$, $B(s_t) = B_1^{-1}(s_t)B_2(s_t)$ and $C(s_t) = B_1^{-1}(s_t)C_1(s_t)$. $G(\cdot)$ can capture the regime-dependent conditional variance. But it is not needed for model classification. Both Cho (2016) and Foerster et al. (2016) emphasize that A may well depend on future regime s_{t+1} in DSGE models with microfoundation subject to regime-switching. Using the perturbation method, Foerster et al. (2016) derive a general form of linearized Markov-switching DSGE models, which can also be written as (12).

Solution Forms and Restrictions

$$x_t = [\Omega(s_t)x_{t-1} + \Gamma(s_t)z_t] + w_t : \text{General RE solution}, \quad (14)$$

$$x_t = \Omega(s_t)x_{t-1} + \Gamma(s_t)z_t : (w_t = 0_{n \times 1}) : \text{MSV solution}, \quad (15)$$

$$w_t = E_t[F(s_t, s_{t+1})w_{t+1}] : (w_t \neq 0_{n \times 1}) : \text{Sunspot component} \quad (16)$$

$$\Omega(s_t) = \{I_n - E_t[A(s_t, s_{t+1})\Omega(s_{t+1})]\}^{-1}B(s_t), \quad (17)$$

$$\Gamma(s_t) = \{I_n - E_t[A(s_t, s_{t+1})\Omega(s_{t+1})]\}^{-1}C(s_t) + E_t[F(s_t, s_{t+1})\Gamma(s_{t+1})R(s_{t+1})], \quad (18)$$

$$F(s_t, s_{t+1}) = \{I_n - E_t[A(s_t, s_{t+1})\Omega(s_{t+1})]\}^{-1}A(s_t, s_{t+1}). \quad (19)$$

Complete Set of MSV solutions and Mean-square Stability: The following matrices will be needed to define mean-square stability and exposition.

$$\begin{aligned} \bar{\Psi}_{G \otimes H} &= [p_{ji}(G(j, i)')^T \otimes H(j, i)], \\ \Psi_{G \otimes H} &= [p_{ij}(G(i, j)')^T \otimes H(i, j)], \end{aligned}$$

where $G = G(s_t, s_{t+1})$ and $H = H(s_t, s_{t+1})$ are $n \times n$ matrices and the arguments of $\bar{\Psi}_{G \otimes H}$ and $\Psi_{G \otimes H}$ are ij -th $n^2 \times n^2$ block. ' and T denote a conjugate and non-conjugate transpose operator, respectively.

Since $F(\cdot)$ and $\Gamma(\cdot)$ are uniquely associated with a given $\Omega(\cdot)$, the full set of MSV solutions can be defined by $\Omega(\cdot)$ as:

$$\mathcal{S} = \left\{ \begin{array}{l} \Omega_h(s_t) \in \mathcal{C}^{n \times n} | \Omega_h(\cdot) \text{ solves (17), } h = 1, \dots, N, \text{ and} \\ \rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) \leq \dots \leq \rho(\bar{\Psi}_{\Omega_h \otimes \Omega_h}) \leq \dots \leq \rho(\bar{\Psi}_{\Omega_N \otimes \Omega_N}) \end{array} \right\}, \quad (20)$$

where $\bar{\Psi}_{\Omega \otimes \Omega}$, and $\Psi_{F \otimes F}$ are defined as:

$$\begin{aligned} \bar{\Psi}_{\Omega \otimes \Omega} &= \begin{bmatrix} p_{11}(\Omega(1)')^T \otimes \Omega(1) & \dots & p_{S1}(\Omega(1)')^T \otimes \Omega(1) \\ \dots & \dots & \dots \\ p_{1S}(\Omega(S)')^T \otimes \Omega(S) & \dots & p_{SS}(\Omega(S)')^T \otimes \Omega(S) \end{bmatrix}, \\ \Psi_{F \otimes F} &= \begin{bmatrix} p_{11}(F(1, 1)')^T \otimes F(1, 1) & \dots & p_{1S}(F(1, S)')^T \otimes F(1, S) \\ \dots & \dots & \dots \\ p_{S1}(F(S, 1)')^T \otimes F(S, 1) & \dots & p_{SS}(F(S, S)')^T \otimes F(S, S) \end{bmatrix} \end{aligned}$$

Only these two matrices will be used for our classification result.

Definition 2 A MSV solution (15) is mean-square stable (MSS) if and only if $\rho(\bar{\Psi}_{\Omega \otimes \Omega}) < 1$. $x_t = \Omega_1(s_t)x_{t-1} + \Gamma_1(s_t)z_t$ is an MOD solution, the most stable solution in the mean-square stability sense if $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) = \min \rho(\bar{\Psi}_{\Omega \otimes \Omega})$ for all $\Omega(s_t) \in \mathcal{S}$ in (20).

3.2 The MOD Method

Propositions 1 and 2 are new to the literature, leading to Proposition 3, the main classification result of the *MOD* method for MSRE models.

3.2.1 Classification of MSRE Models by the *MOD* Method

Proposition 1 *There is no mean-square stable sunspots w_t satisfying (16) if and only if $\rho(\Psi_{F \otimes F}) \leq 1$.*

Proposition 2 *For all $\Omega_h(s_t) \in S$,*

1. $\rho(\bar{\Psi}_{\Omega_h \otimes \Omega_h})\rho(\Psi_{F_1 \otimes F_1}) \geq 1$, $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1})\rho(\Psi_{F_h \otimes F_h}) \geq 1$.
2. $\Omega_1(s_t)$ is the unique real-valued *MOD* solution if $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1})\rho(\Psi_{F_1 \otimes F_1}) < 1$.

Proposition 3 *Consider a MSRE model (12) and the set of solutions \mathcal{S} in (20). Then, necessary and sufficient conditions for determinacy, indeterminacy and the case of no stable solution in the mean-square stability sense are given in Table (3). Moreover, if there exists a solution such that $\rho(\bar{\Psi}_{\Omega \otimes \Omega})\rho(\Psi_{F \otimes F}) < 1$, it is the unique real-valued *MOD* solution and the model is determinacy-admissible.*

Table 3: **Classification of MSRE Models**

| | Determinacy-Admissible(DA) $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1})\rho(\Psi_{F_1 \otimes F_1}) < 1$ | Determinacy-Inadmissible(DIA) $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1})\rho(\Psi_{F_1 \otimes F_1}) \geq 1$ |
|--------------------|--|--|
| Determinacy | $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) < 1$, $\rho(\Psi_{F_1 \otimes F_1}) \leq 1$ | Impossible |
| Indeterminacy | $\rho(\Psi_{F_1 \otimes F_1}) > 1$ | $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) < 1$ |
| No Stable Solution | $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) \geq 1$ | $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) \geq 1$ |

Corollary 2 *The uniqueness of a mean-square stable MSV solution does not always imply determinacy in MSRE models with lagged variables. That is, a model can be determinacy even when $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1}) < 1 \leq \rho(\bar{\Psi}_{\Omega_2 \otimes \Omega_2})$ because this can be compatible with $\rho(\Psi_{F_1 \otimes F_1}) > 1$.*

Remark. Corollary 2 is an important and new finding in the literature. LRE models with lagged variables, the uniqueness of a MSV solution implies determinacy. In stark contrast, it is not the case for MSRE models.

3.3 Implementing MOD Method for MSRE Models

The methodology is completed by finding the *MOD* solution, Partitioning the entire class of MSRE models by determinacy-admissibility(DA) and determinacy-inadmissibility(DIA) provide an important identification condition for the *MOD* solution. This is crucial in practical application. There are two main matlab codes for MSRE models.

- `fmsre.m` : Implements the *MOD* method using the modified forward method.
- `gbmsre.m` (for Windows users) or `gbmsre_mac.m` (for Mac users) : Implements the *MOD* method using the Gröbner basis (GB).

3.3.1 Implementing the Forward Method

1. Write your model in the form of (12), e.g., “Ex.m”. Construct P and $A(\cdot)$. Construct $B(\cdot)$, $C(\cdot)$ or $R(\cdot)$ if any.
2. Type and run `[DETC, FCC, OmegaK]=fmsre(P,A,B,..)`. Other input and output arguments will be explained later.

$$DETC = [\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) \quad \rho(\Psi_{F^* \otimes F^*}) \quad \rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) \rho(\Psi_{F^* \otimes F^*})].$$

- (a) If $DETC(3) < 1$, then $\Omega^*(s_t) = \Omega_1(s_t)$, and the model is DA. $DETC(1)$ and $DETC(2)$ tells whether the model is DET/INDET/NSS from Proposition 3. Done.
 - (b) If $DETC(3) \geq 1$ and $\rho(\Omega^*) < 1$, the model is indeterminate. Done. No need to check whether $\Omega^*(\cdot)$ is the *MOD* solution.
 - (c) If $DETC(3) = NaN$ (forward solution does not exists), or if $DETC(3) \geq 1$ and $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) \geq 1$, the forward method cannot tell the classification.
3. If (c) occurs, use the GB approach. Refer to the implementation procedure below.

As we keep emphasizing, the forward method would be self-sufficient if one considers economic models, which would almost surely be determinacy-admissible. That is, one would encounter only Case a because the remaining cases would imply that the model is determinacy-inadmissible. Therefore, the GB approach would not be required in practice.

3.3.2 Implementing the Gröbner Basis.

gbmsre.m or gbmsre_mac.m does not directly apply the Gröbner basis in matlab. Actual computation is done in the language called Singular.

For Windows Users

1. Preparation

- (a) Install Singular following a default option from <https://www.singular.uni-kl.de/index.php/singular-download.html>. (It will be installed at c:\cygwin64\ home \ Computername where Computername is your computer name, which is automatically identified.).
- (b) Open Cygwin64 Terminal and type 'singular' in that command window.

2. Implementing the GB technique

- (a) Write your model in the form of (12), e.g., "Ex.m". Construct P , A and B.
- (b) Type and run DETCMOD=gbmsre(P,A,B) : This will produces a file GB_singular.ascii at the directory above, which transforms the restriction (17) as a set of polynomials in Singular language. And it will display the following message in matlab command window.

```
execute(read("GB_singular.ascii")); timer; ns;
```

The code will temporarily hold. Copy and Paste the expression above in Singular command line, and press the Enter key. Then, Singular will read GB_singular.ascii, computes the Gröbner basis and stores all the solutions at the directory above as Sol_partC.txt and Sol_partC.txt. If a command prompt ">" shows up in Singular, computation is done. The first number shown is the computation time in milliseconds. The second is the number of solutions.

- (c) Come back to matlab window and press any key. Then "Ex.m" will load the Singular output files, transform them into the solution format in matlab, report the total number of solutions, the MOD and all other MSV solution, and the information in Table 3.

3. Interpretation of the Results and Completing Classification

- (a) Your code “Ex.m” will produce a table with an $N \times 4$ matrix DETC.

$$\text{DETC} = [\rho(\bar{\Psi}_{\Omega_h \otimes \Omega_h}) \rho(\Psi_{F_h \otimes F_h}) \rho(\bar{\Psi}_{\Omega_h \otimes \Omega_h}) \rho(\Psi_{F_h \otimes F_h}) \rho(\Psi_{\Omega'_h \otimes F_h})], h = 1, \dots, N.$$
- (b) The first row is the result for the *MOD* solution. Follow Table 3 for classification.

For Mac Users

1. Preparation

- (a) Installation: Follow the instruction below carefully. “Applications” is the work directory.
- i. Go to System Preferences and open Security & Privacy in your mac computer. Allow apps downloaded from “Open anyway”.
 - ii. Go to <https://www.singular.uni-kl.de/index.php/singular-download.html>. Choose OS X and Choose the option “Installation from a dmg File”, and follow the instruction there.
- (b) Open **Singular** command window: Same as Windows

2. Implementing the GB technique: Same as Windows except the following.

- (b) Type and run DETCMOD=gbmsre_mac(P,A,B). The message is as follows.
- ```
execute(read("/Applications/GB_singular.ascii")); timer; ns;
```

### 3. Same as Windows

# Appendix

## A Set of Matlab Codes for LRE and MSRE Models

The package named as “MODmethodyyyymmdd” contains several folders.

1. MODMethod: This folder has two subfolders LRE and MSRE containing the following set of main codes and supplementary ones.

|               | LRE                                                                              | MSRE                                                                                                                                                                                                                   |
|---------------|----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

In what follows, main codes are explained in detail. Supplementary codes for the MOD methodology are briefly explained as it is self-explanatory. Finally, examples are explained.

## A.1 MOD Method - LRE Models

### A.1.1 Main Codes

#### qzmlre.m

This is the main code implementing the *MOD* method using the eigensystem, the QZ decomposition. `qzmlre` stands for the QZ method for LRE models. The code adopts some routines such as `reorder.m` and `qzswitch.m` in the package of Sims (2002), but applies to our representation of LRE models.

[DETCMOD, OmegaMOD, GammaMOD, FMODE, Geig, gvAll, OmegaAll, GammaAll, FAll]=qzmlre(A,B,C,R)

#### • Input Arguments:

| Input | format              | Concepts | Default                       |
|-------|---------------------|----------|-------------------------------|
| A     | $n \times n$ matrix | $A$      | Required                      |
| B     | $n \times n$ matrix | $B$      | Optional $B = 0_{n \times n}$ |
| C     | $n \times m$ matrix | $C$      | Optional $C = I_{n \times n}$ |
| R     | $m \times m$ matrix | $R$      | Optional $R = 0_{n \times n}$ |

#### • Output Arguments:

| Output   | Format                  | Concepts                                                                                   |
|----------|-------------------------|--------------------------------------------------------------------------------------------|
| DETCMOD  | $1 \times 3$ vector     | DETCMOD = $[\rho(\Omega_1) \ \rho(F_1) \ \rho(\Omega_1)\rho(F_1)]$                         |
| OmegaMOD | $n \times n$ matrix     | OmegaMOD = $\Omega_1$ ( <i>MOD</i> solution)                                               |
| GammaMOD | $n \times n$ matrix     | GammaMOD = $\Gamma^1$ ( <i>MOD</i> solution)                                               |
| FMODE    | $n \times n$ matrix     | FMODE = $F_1$ ( <i>MOD</i> solution)                                                       |
| Geig     | $2n \times 1$ vector    | Vector of the generalized eigenvalues                                                      |
| gvAll    | $N \times n$ matrix     | $N = \#$ of MSV solutions. Each row is the choice $n$ out of $2n$ generalized eigenvalues. |
| OmegaAll | $N \times 1$ cell array | $i$ -th solution is associated with $i$ -th <b>gvAll</b> . $1 \leq i \leq N$               |
| GammaAll | $N \times 1$ cell array | Same as above                                                                              |
| FAll     | $N \times 1$ cell array | Same as above                                                                              |

**Note.** If  $\rho(\Omega_1)\rho(F_1) > 1$ , then  $\Omega(\xi_1, \dots, \xi_n) \notin \mathcal{S}$ .

- **Interpreting the Results:** Refer to Table 1 or 2.

**fmlre.m:**

This is the main code implementing the *MOD* method using the modified forward method. fmlre stands for the forward method for LRE models.

[DETC, FCC, OmegaK, GammaK, FK, OtherOutput, IRS]=fmlre(A,B,C,R,Opt);

- **Input Arguments:** Same as those of qzmlre.m. In addition, there is an optional input, Opt. See the code for detail.
- **Output Arguments:**

| Output      | Format               | Concepts                                                                |
|-------------|----------------------|-------------------------------------------------------------------------|
| DETC        | $1 \times 3$ vector  | $DETC = [\rho(\Omega^*) \quad \rho(F^*) \quad \rho(\Omega^*)\rho(F^*)]$ |
| FCC         | $1 \times 2$ vector  | $FCC = [K \quad \rho(R' \otimes F^*)]$ , $K$ is # of forward iteration  |
| OmegaK      | $n \times n$ matrix  | $\Omega K = \Omega^*$                                                   |
| GammaK      | $n \times n$ matrix  | $\Gamma K = \Gamma^*$ if $FCC2 < 1$<br>$= \Gamma$ if $FCC2 > 1$         |
| FK          | $n \times n$ matrix  | $FK = F^*$                                                              |
| OtherOutput |                      | Other output arguments: See the code for details                        |
| IRS         | $T \times nm$ matrix | Impulse-response function with horizon $T$ .                            |

- Interpretation of DETC. Refer to Table 1
  1. If  $DETC(3) = \rho(\Omega^*)\rho(F^*) < 1$ , then the model is determinacy-admissible and  $\Omega^* = \Omega_1$ . DETC(1) and DETC(2) tells whether the model is DET/INDET/NSS. Done.
  2. If  $DETC(3) \geq 1$  and  $\rho(\Omega^*) < 1$ , the model is indeterminate.
  3. If  $DETC(3) \geq 1$  and  $\rho(\Omega^*) \geq 1$ , or  $DETC(3) = \text{NaN}$  ( $\Omega^*$  does not exist), then use qzmlre.m to find the *MOD* solution.

**Remark 1.** If  $FCC(2) < 1$ ,  $\Gamma K = \Gamma^*$  and therefore,  $\Omega K$  and  $\Gamma K$  constitute the forward solution. If  $FCC(2) \geq 1$ , the FCC condition is violated. Thus even if  $\Omega^*$  exists, a correct interpretation is that there is no forward solution because  $\Gamma^*$  does not exist. The

code still produces  $\Gamma$  using the formula (6), which is rejected as an RE equilibrium on the ground of the NBC criterion. Refer to Cho and McCallum (2015) for detail.<sup>1</sup>

### A.1.2 Supplementary Codes: Auxiliary Functions

#### qzmlre2gensys.m

This code makes gensys algorithm of Sims (2002) comparable to qzmlre.m and fmlre.m. Specifically, for given matrices  $A, B$  and  $C$  in (1a), define

$$k_t = E_t x_{t+1}, \quad x_t = k_{t-1} + \eta_t \quad (21)$$

Then the model can be written as

$$\Gamma_0 \hat{y}_t = \Gamma_1 \hat{y}_{t-1} + \Pi z_t + \Psi \eta_t \quad (22)$$

where  $\hat{y}_t = [k'_t \ x'_t]'$  and  $\Gamma_0, \Gamma_1, \Pi$  and  $\Psi$  are the input matrices of gensys algorithm as functions of  $A, B$  and  $C$  such that:

$$\Gamma_0 = \tilde{A}, \quad \Gamma_1 = \tilde{B}, \quad \Pi = \begin{bmatrix} 0_{n \times m} \\ C \end{bmatrix}, \quad \Psi = \begin{bmatrix} I_n \\ 0_{n \times n} \end{bmatrix}$$

where  $\tilde{A}$  and  $\tilde{B}$  are defined in (10). It is conventional to define  $k_t$  manually to include only non-zero expectational variables in vector  $\hat{y}_t$  so that the dimension of these matrices are less than  $2n$  if  $A$  has a rank less than  $n$ . Although (22) has a larger dimension in general, it makes the transformation model-independent, thus one does not need to write a given model in the form of gensys input manually. The gensys algorithm computes the generalized eigenvalues  $\xi$  with respect to the matrix pencil  $[\Gamma_0 - \xi \Gamma_1]$  via the Schur decomposition theorem, which is exactly the same as  $[\tilde{A} - \xi \tilde{B}]$ . The algorithm examines the existence of the unique stable solution by what is known as spanning conditions. The code has the following form:

```
[G1,C,impact,fmat,fwt,ywt,gev,eu,loose]=qzmlre2gensys(A,B,C,c,div)
```

- **Input Arguments:**  $A, B, C$  are the same as those of fmlre.m and qzmlre.m.  $c$  and  $div$  are optional input arguments of gensys.m.

---

<sup>1</sup>What it means by  $FCC(2) > 1$  can be understood as follows. The situation is like  $FCC(2) = |r| > 1$  where  $\Gamma_k = \sum_{i=1}^k r^{k-i}$ , which explodes thus does not exist. The formula (6) is like  $1/(1-r) < 0$  when  $r > 1$ , which is clearly wrong.

- **Output Arguments:** Outputs are the same as those of `gensys.m`.
- **Interpreting the Results:** Follow the code `gensys.m`. A key result is the vector `eu`, which shows the existence and uniqueness. The conditions for the classification by the `gensys` and the corresponding conditions by the *MOD* solution can be stated as follows.

| Classification     | <code>eu</code>           | <i>MOD</i>                             |
|--------------------|---------------------------|----------------------------------------|
| Determinacy        | [1 1]                     | $\rho(\Omega_1) < 1, \rho(F_1) \leq 1$ |
| Indeterminacy      | [1 0]                     | $\rho(\Omega_1) < 1, \rho(F_1) > 1$    |
| No Stable Solution | <code>eu(1) &lt; 1</code> | $\rho(\Omega_1) \geq 1$                |

The *MOD* conditions are those by pulling the DA and DIA partitions in Table (1).

### A.1.3 Supplementary Codes: Examples

#### **modlre\_sample.m**

This code applies the three solution techniques to 7 atheoretical models belong to DA-DET, DA-INDET, DA-NSS, DIA-INDET(real- and complex-valued *MOD* solution) and DIA-NSS(real- and complex-valued *MOD* solution). This shows that `qzmlre.m` is a stand-alone procedure. The code also shows that `fmlre.m` is equivalent to `qzmlre.m` except for DIA model with complex-valued solutions. DIA models are not economic ones and taken from Sims (2007).

1. **Instruction** : Choose one of the seven models (See the instruction of the code.) and run it. This code automatically implements the forward method followed by the QZ approach using an auxiliary code `modlre_FM_QZ.m`. One can manually choose `fmlre.m` or `qzmlre.m`.

#### **methods\_comparison\_LRE.m**

This code shows the equivalence between QZ method (`qzmlre.m`), the sequential technique (`fmlre.m` and `qzmlre.m` if necessary) and `gensys` algorithm (`qzmlre2gensys.m`) for all 7 examples above. Simply run the code.

## A.2 MSRE Models

### A.2.1 Main Codes

#### **fmmsre.m**

This is the main matlab code implementing the *MOD* method using the modified forward method (explained below). It takes  $P$ ,  $A(s_t, s_{t+1})$  and optional  $B(s_t)$ ,  $C(s_t)$  or  $R(s_t)$  as input arguments and produces the following output: conditions for determinacy, indeterminacy or the case of no stable solution, forward convergence condition (FCC), the forward solution and others. The function format, input and main outputs are given in the following way.

$$[\text{DETC}, \text{FCC}, \text{OmegaK}, \text{GammaK}, \text{FK}, \text{OtherOutput}, \text{IRS}] = \text{fmmsre}(P, A, B, C, R, \text{Opt});$$

where `fmmsre` stands for the forward method for MSRE models. ( $\text{OmegaK} = \Omega^*(s_t)$ ,  $\text{GammaK} = \Gamma^*(s_t)$ ,  $\text{FK} = F^*(s_t, s_{t+1})$ )

#### • Input Arguments:

| Input | format                                                | Concepts                                                                                  | Default                              |
|-------|-------------------------------------------------------|-------------------------------------------------------------------------------------------|--------------------------------------|
| P     | $S \times S$ matrix                                   | $P(i,j) = P(s_{t+1} = j   s_t = i)$                                                       | Required                             |
| A     | $S \times S$ cell array or<br>$S \times 1$ cell array | $A\{i,j\} = A(s_t = i, s_{t+1} = j)$ or<br>$A\{i,1\} = A(s_t = i)$ if $A(\cdot) = A(s_t)$ | Required                             |
| B     | $S \times 1$ cell array                               | $B\{i,1\} = B(s_t = i)$                                                                   | Optional $B\{i,1\} = 0_{n \times n}$ |
| C     | $S \times 1$ cell array                               | $C\{i,1\} = C(s_t = i)$                                                                   | Optional $C\{i,1\} = I_{n \times n}$ |
| R     | $S \times 1$ cell array or<br>$m \times m$ matrix     | $R\{i,1\} = R(s_t = i)$ or<br>$R = R$                                                     | Optional $R = 0_{n \times n}$        |
| Opt   | Other optional input arguments: See the code          |                                                                                           |                                      |

**Remark 1.** To conduct impulse-response analysis, we recommend to specify  $C(s_t) = B_1^{-1}(s_t)C_1(s_t)$ .

**Remark 2.** Specify optional inputs as `[]` if they are followed by other inputs. For instance, set `B=[]`; `C=[]`; to specify `R` and/or `Opt`.

• **Output Arguments:**

| Output           | Format                                           | Concepts                                                                                                                                                                                        |
|------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DETC             | $1 \times 4$ vector                              | $[\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) \ \rho(\Psi_{F^* \otimes F^*}) \ \rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) \ \rho(\Psi_{\Omega'^* \otimes F^*})]$ |
| FCC              | $1 \times 2$ vector                              | $[K \ \rho(\Psi_{R' \otimes F^*})]$ , $K$ is # of forward iteration                                                                                                                             |
| OmegaK           | $S \times 1$ cell array                          | $\text{OmegaK}\{i,1\} = \Omega^*(s_t)$                                                                                                                                                          |
| GammaK           | $S \times 1$ cell array                          | $\text{GammaK}\{i,1\} = \Gamma^*(s_t)$ if $\text{FCC2} < 1$<br>$= \Gamma(s_t)$ if $\text{FCC2} > 1$                                                                                             |
| FK               | $S \times S$ cell array                          | $\text{FK}\{i,j\} = F^*(s_t, s_{t+1})$                                                                                                                                                          |

• Interpretation of DETC. Refer to Table 3

1. If  $\text{DETC}(3) = \rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) < 1$ , then the model is determinacy-admissible and  $\Omega^* = \Omega^{MOD}$ .
2. If  $\text{DETC}(3) \geq 1$  and  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) < 1$ , the model is indeterminate.
3. If  $\text{DETC}(3) \geq 1$  and  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) \geq 1$ , or  $\text{DET}(3) = \text{NaN}$  ( $\Omega^*(s_t)$  does not exist), then use `gbmsre.m` to find the *MOD* solution.

**Remark 3.** There is an additional condition in DETC,  $\rho(\Psi_{\Omega'^* \otimes F^*})$  unlike the LRE models. Recall that  $\text{DETC} = [\rho(\Omega^*) \ \rho(F^*) \ \rho(\Omega^*)\rho(F^*)]$  in LRE models where  $\rho(\Omega^*)\rho(F^*) = \rho(\Omega'^* \otimes F^*)$ . In MSRE models,  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) < 1$  implies that  $\rho(\Psi_{\Omega'^* \otimes F^*}) < 1$  but the converse is not true. This is the major difference between the two types of models. This is precisely the reason why the uniqueness of a stable MSV solution does not mean determinacy in general. In fact, such a case can always be generated by the order-preserving transformation of the model as long as the *MOD* solution is stable in DIA model such that  $\rho(\Psi_{\Omega_1 \otimes F_1}) < 1$  but  $\rho(\bar{\Psi}_{\Omega_1 \otimes \Omega_1})\rho(\Psi_{F_1 \otimes F_1}) > 1$ . Refer to Corollary 2.

**Remark 4.** If  $\text{FCC}(2) < 1$ ,  $\text{GammaK} = \Gamma^*(s_t)$  and therefore, **OmegaK** and **GammaK** constitute the forward solution. If  $\text{FCC}(2) \geq 1$ , the FCC condition is violated. Thus there is no well-defined forward solution even if  $\Omega^*(s_t)$  exists. The code still produces  $\Gamma(s_t)$  using the formula (6), which is rejected as an RE equilibrium on the ground of the NBC criterion. Refer to Cho (2016) for detail.

### gbmsre.m or gbmsre\_mac.m

**gbmsre.m** is the main matlab code implementing the *MOD* method using the Gröbner basis approach in Windows. Mac users must use **gbmsre\_mac.m**. It plays the same role as **qzmlre.m** for LRE models but identifies the *MOD* solution by computing all MSV solutions. It takes the same input  $P$ ,  $A(s_t, s_{t+1})$  and  $B(s_t)$  as those of **fmsre.m** where a non-zero  $B(s_t)$  for at least one regime must be included. The code produces the following output: conditions for determinacy, indeterminacy or the case of no stable solution. The function format, input and main outputs are given in the following way.

$$[\text{DETCMOD}, \text{OmegaMOD}, \text{FMOD}, \text{DETC\_All}, \text{AllOmegas}] = \text{gbmsre}(P, A, B);$$

where **gbmsre** stands for the Gröbner basis method for MSRE models. ( $\text{OmegaMOD} = \Omega_1(s_t)$ ,  $\text{FMOD} = F_1(s_t, s_{t+1})$ ).

Unlike **fmsre.m**, this code uses the language called “Singular”, which must be installed in advance. Therefore, one must manually follow the step displayed in the matlab command window.

- **Input Arguments:** same as those of **fmsre.m** but  $P$ ,  $A$  and  $B$  must be specified because the purpose of this code is to find all MSV solutions when lagged variables are present with  $B \neq 0_{n \times n}$ .
- **Output Arguments:**

| Output    | Format                  | Concepts                                                                                                                                                                                                                                                                                                                                                                     |

### A.2.2 Supplementary Codes: Auxiliary Funtions

#### lambda\_min.m

For a given  $F(s_t, s_{t+1})$ , this code computes  $\Lambda_m(s_t, s_{t+1})$  such that  $\rho(\Psi_{F \otimes F})\rho(\bar{\Psi}_{\Lambda_m \otimes \Lambda_m}) = 1$  following the analytical form presented in Proposition 1 of Cho (2021). This is important because it states that there exists no mean-square stable sunspot components associated with a given  $F(s_t, s_{t+1})$  if and only if  $\rho(\Psi_{F \otimes F}) \leq 1$ . This improves Lemma 2 of Cho (2016). This code just confirms that Proposition 1 holds numerically. In fact, the  $\rho(\Psi_{F \otimes F})\rho(\bar{\Psi}_{\Lambda \otimes \Lambda}) \geq 1$  for all possible  $\Lambda(s_t, s_{t+1})$  is the relation that Farmer et al. (2009) wants to verify this numerically but not completely. Proposition 1 proves their conjecture by providing an analytical form of  $\Lambda_{\min}(s_t, s_{t+1})$ . If one wants to compute  $\Lambda_{\min}(\cdot)$  for history-dependent sunspots, define  $s_{q,t}$ ,  $P_q$  and  $F(s_{q,t}, s_{q,t+1})$  following Cho (2021) and use the latter two as input arguments.

The function format is given by

$$[\text{Lmin}, \text{tau2}, \text{xi2}, \text{V}, \text{D}, \text{u}, \text{Q}] = \text{lambda\_min}(\text{P}, \text{F})$$

- **Input Arguments:** The code takes P and F as input arguments.

### A.2.3 Supplementary Codes: Examples

Examples are for Windows users. Mac Users must use `gbmsre_mac.m`. To do so, replace `gbmsre.m` with `gbmsre_mac.m` in the codes `modmsre_sample.m`, `modmsre_FM_GB.m`, `Example_for_Corollary2.m` and `computation_time_comparison.m`.

#### **modmsre\_sample.m**

This code applies the three solution techniques to 7 atheoretical models belong to DA-DET, DA-INDET, DA-NSS, DIA-INDET(real- and complex-valued *MOD* solutions) and DIA-NSS(real- and complex-valued *MOD* solutions). The code also shows that `fmsre.m` is equivalent to `modmsre_FM_GB.m` except for DIA model with complex-valued solutions. Choose one of the seven models (See the instruction of the code.) and run it. This code automatically implement the forward method followed by the GB approach using an auxiliary code `modmsre_FM_GB.m`. One can manually choose `fmsre.m` or `gbmsre.m`.

#### **lambda\_min.Example.m**

Sample code for using `lambda_min.m`: Finding  $\Lambda_m$  is not required as it is proven in Proposition 1. This code just shows how the formula works numerically. Simply run it.

#### **Example\_for\_Corollary2.m**

This code shows an example in which the model has a unique stable MSV solution but is indeterminate. The sample model is randomly generated, which implies that this is not a rare event, but an intrinsic property of MSRE models. Just run it.

#### **computation\_time\_comparison.m**

This code compares the computation time for 4 solution methods: QZ method, gensys and FM for LRE models, and FM for MSRE models. Random atheoretical determinacy-admissible models of dimension  $N$  and  $S$  are generated and the code reports average computation time over  $T$  trials. Set  $N$ ,  $S$ , and  $T$  at the beginning and run it. Then it will show the computation time for the four cases for  $n = 1, \dots, N$ .

#### **GBmsre\_Testing\_computation\_time.m or GBmsre\_Testing\_computation\_time\_mac.m**

This code shows that the computation time to compute all MSV solutions using the Gröbner basis approach increases exponentially as the dimension of the model, number of lagged variables and the number of regimes increase.

**Instruction:** Set  $S = 1$ ,  $n$  and  $m$  for LRE models and set  $S = 2$  or  $3$ ,  $n$  and  $m$  for MSRE models. Read the instruction of the code or the code explanation in the following section.

We first show that the technique can be applied to LRE models as if no eigensystem were available. Then one can also infer how tough to apply this approach to MSRE models.

### A. Gröbner basis approach for LRE models

For LRE models, the problem of computing all MSV solutions boils down to the system of polynomial equations implied by

$$A\Omega^2 - \Omega + B = 0_{n \times n}.$$

Vectorizing this implies that there are  $n^2$  quadratic equations in  $n^2$  unknown  $\omega_{ij}$ , which is the  $(i, j)$ -th element of  $\Omega$ . When some of elements of  $B$  are zeros, the number of unknowns can be reduced. For simplicity, let  $m$  be the rank of  $B$  and construct arbitrary  $B$  such that the first  $n - m$  columns are  $n \times (n - m)$  matrix of zeros. The code `gbmsre.m` can also handle the LRE models by setting  $P = 1$  and  $S = 1$ . Let  $Model(n, m)$  denotes a LRE model with an  $n$  dimensional model and  $m$  being the rank of  $B$ . Then, the number of MSV solutions is  $N = \frac{(n+m)!}{m!n!}$  as it is the same as the number of combination of choosing  $n$  out of  $2n - (n - m) = n + m$ . This can be derived from Generalized Schur Decomposition. Refer to `qzmlre.m` for detail.

The code `GBmsre_Testing_computation_time.m` computes the solution to a model specified by  $P, n$  and  $m$  using `gbmsre.m`. For an LRE model, set  $P = 1$ . The code generates  $n \times n$  matrices  $A$  and  $B$  of random numbers such that the rank of  $B$  is  $m$ . Table 4 shows that the number of seconds required to compute the all solutions to  $Model(n, m)$ . The case of  $m = 1$  is instructive because the number of  $N = n + 1$ . The number of ideals implied by the system of the polynomial equations is equal to the total number of solutions. Gröbner basis approach is a way of finding these ideals, and therefore, we can infer how long it would take as the number of unknowns increases by one. Table 4 indicates that the computation time increases by a factor of around  $2^N$ . This is the source of the problem why finding all solutions to a polynomial is difficult.

For  $Model(n \geq 2, m = 2)$ , the number of solutions explodes and it takes about 10 minutes for  $Model(6, 2)$  but computation fails to yield the solution as  $n \geq 7$ . The most general model that the Gröbner basis approach is successful is  $Model(4, 3)$ .  $N.A$  in Table 4 is this case where `gbmsre.m` stops computation because of lack of memory within a day. Of course, when the structure of the model is simpler, the Gröbner basis technique may work for higher dimensional models, for instance, the rank of  $A$  is less than  $n$ , but this simulation exercise

Table 4: **Computation Time for Gröbner basis in LRE Models**

| $n$ | $m$ | $N$ | Seconds       | $n$ | $m$ | $N$ | Seconds        |
|-----|-----|-----|---------------|-----|-----|-----|----------------|
| 1   | 1   | 2   | < 1           | 2   | 2   | 6   | < 1            |
| 2   | 1   | 3   | < 1           | 3   | 2   | 10  | < 1            |
| 3   | 1   | 4   | < 1           | 4   | 2   | 15  | $\approx 1$    |
| 9   | 1   | 10  | $\approx 1.5$ | 5   | 2   | 21  | $\approx 7$    |
| 10  | 1   | 11  | $\approx 3$   | 6   | 2   | 28  | $\approx 548$  |
| 11  | 1   | 12  | $\approx 4$   | 7   | 2   | 36  | <i>N.A</i>     |
| 12  | 1   | 13  | $\approx 12$  | 3   | 3   | 20  | $\approx 3$    |
| 13  | 1   | 14  | $\approx 35$  | 4   | 3   | 35  | $\approx 4500$ |
| 14  | 1   | 15  | $\approx 95$  | 5   | 3   | 252 | <i>N.A</i>     |
| 15  | 1   | 16  | $\approx 208$ | 4   | 4   | 70  | <i>N.A</i>     |

shows that it is extremely difficult to use this approach for non-trivial economic models.

### B. Gröbner basis approach for MSRE models

The problem is much more serious for MSRE models. Indeed, the model can be stated as  $Model(n, m, S)$  where  $S$  is the number of regimes. There is no analytical form for  $N$ , the number of MSV solutions but  $N \geq \prod_{s=1}^S \frac{(n+m_s)!}{m_s!n!}$  in general. This is because when  $P = I_S$ , each regime collapses to  $Model(n, m_s)$ . Thus the minimum number of solution is the product of the number of solutions at each regime. For instance,  $Model(n, n) = 2, 6, 20, \dots$  for  $n = m = 1, 2, 3, \dots$ . Therefore,  $N \geq 4, 36, 400, \dots$  for MSRE models  $Model(n, n, S)$ . This implies that the computation time will increase more than  $2^4, 2^{36-4}, 2^{400-36}$ . Indeed the method works extremely fast for  $Model(1, 1, 2)$  with  $N = 4$ , and it takes several minutes for  $Model(2, 2, 2)$  with  $N = 44 > 36$ . However, computation fails for  $Model(3, 3, 2)$ . Table 5 shows the MSRE models for which Gröbner basis works and does not work.

Table 5: **Computation Time for Gröbner basis in MSRE Models**

| $n$ | $m$ | $S$ | $N$ | Seconds       | $n$ | $m$ | $S$ | $N$        | Seconds       |
|-----|-----|-----|-----|---------------|-----|-----|-----|------------|---------------|
| 1   | 1   | 2   | 4   | < 1           | 2   | 2   | 2   | 44         | $\approx 227$ |
| 2   | 1   | 2   | 9   | < 1           | 3   | 2   | 2   | <i>N.A</i> | <i>N.A</i>    |
| 3   | 1   | 2   | 16  | < 1           | 1   | 1   | 3   | 8          | < 1           |
| 4   | 1   | 2   | 25  | $\approx 3$   | 2   | 1   | 3   | 27         | $\approx 2$   |
| 5   | 1   | 2   | 36  | $\approx 60$  | 3   | 1   | 3   | 64         | $\approx 592$ |
| 6   | 1   | 2   | 49  | $\approx 573$ | 4   | 1   | 3   | 125        | <i>N.A</i>    |
| 7   | 1   | 2   | 64  | <i>N.A</i>    | 2   | 2   | 3   | <i>N.A</i> | <i>N.A</i>    |

## B Examples

### B.1 Codes for Replicating Cho (2016)

All of the models turn out to be determinacy-admissible and the forward solution is now confirmed by the *MOD* method. Therefore, the results of Cho (2016) is necessary as well as sufficient.

#### B.1.1 The Fisherian Model

**X1.m:** This is a univariate MSRE model without predetermined variables considered by Davig and Leeper (2007) and Farmer et al. (2009):

$$\begin{aligned}\alpha(s_t)\pi_t &= E_t\pi_{t+1} + r_t, \\ r_t &= \rho r_{t-1} + \epsilon_t,\end{aligned}$$

where  $\pi_t$  and  $r_t$  are inflation and the real interest rate, respectively. When  $\alpha(s_t) < (>)1$ , monetary policy is passive (active). The model can be cast in the form of (12) as:

$$x_t = A(s_t)E_tx_{t+1} + C(s_t)z_t, \quad z_t = \rho z_{t-1} + \epsilon_t,$$

where  $x_t = \pi_t$ ,  $z_t = r_t$ ,  $A(s_t) = C(s_t) = 1/\alpha(s_t)$ ,  $B(s_t) = 0$  and  $R = \rho$ . The forward solution will be of the form  $x_t = \Gamma^*(s_t)z_t$  if it exists. Let  $\rho = 0.9$ ,  $p_{11} = 0.8$  and  $p_{22} = 0.9$ .

**Case=1:** This is an example of determinacy with  $\alpha(1) = 0.95$  and  $\alpha(2) = 1.5$ . One may write the code as:

```
S=2; p11=0.8; p22=0.9; p12=1-p11; p21=1-p22; P=[p11 p12;p21 p22];
rho=0.9; alpha{1}=0.95; alpha{2}=1.5;
for i=1:S, A{i,1}=1/alpha{i}; C{i,1}=1/alpha{i}; end, R=rho;
[DET, FCC, OmegaK,GammaK,FK]=fmmsre(P,A,[],C,R);
```

The first three lines specify the number of regimes, transition probability matrix and  $A$ ,  $C$  and  $R$ . The last line shows the function “*fmmsre.m*”. Since no lagged variables are present,  $FCC(1)$  holds trivially because there is no forward iteration and so  $FCC1=1$ .  $DET(1) = \rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) = 0$  and  $DET(2) = \rho(\Psi_{F^* \otimes F^*}) = 0.9059 < 1$ .

Since  $\text{DET}(1) \times \text{DET}(2) = 0 < 1$ , the model is determinacy-admissible and the model is determinate. Since  $\text{FCC}(2) = \rho(\Psi_{R' \otimes F^*}) = 0.8014 < 1$ , the forward solution exists, which is given by  $x_t = \Gamma^*(s_t)z_t$ .  $\text{GammaK}\{1,1\}$  representing  $\Gamma^*(1)$  is 6.11 and  $\text{GammaK}\{2,1\} = 2.25$ .

**Case=2:** This is an example of indeterminacy with  $\alpha(1) = 0.9$  and  $\alpha(2) = 1.5$ . Set  $\alpha\{1\}=0.9$  above and run the code. In this case,  $\text{FCC}(1) = 1$ .  $\text{DET}(1) = 0$ .  $\text{DET}(2) = 1.01 > 1$ . The model is determinacy-admissible, but indeterminate.

### B.1.2 Regime-Switching Monetary Policy

**X2.m:** This is the model analyzed in Section 5 of Cho (2016). The model is given by:

$$\pi_t = \beta E_t \pi_{t+1} + \kappa y_t + z_{S,t}, \quad (23)$$

$$y_t = E_t y_{t+1} - \frac{1}{\sigma} (i_t - E_t \pi_{t+1}) + z_{D,t}, \quad (24)$$

$$i_t = (1 - \rho) \phi_\pi(s_t) \pi_t + \rho i_{t-1} + z_{MP,t}. \quad (25)$$

In matrix form,  $x_t = [\pi_t \ y_t \ i_t]'$ ,  $z_t = [z_{S,t} \ z_{D,t} \ z_{MP,t}]'$ ,  $\epsilon_t = [\epsilon_t^S \ \epsilon_t^D \ \epsilon_t^{MP}]'$ , and,

$$B_1(s_t)x_t = A_1(s_t)E_t[x_{t+1}] + B_2x_{t-1} + z_t, \quad z_t = Rz_{t-1} + \epsilon_t,$$

$$B_1(s_t) = \begin{bmatrix} 1 & -\kappa & 0 \\ 0 & 1 & 1/\sigma \\ -(1-\rho)\phi_\pi(s_t) & 0 & 1 \end{bmatrix}, \quad A_1(s_t) = \begin{bmatrix} \beta & 0 & 0 \\ 1/\sigma & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \rho \end{bmatrix}.$$

The matrix  $R$  is now a matrix of zeros. Then the model is given by:

$$x_t = A(s_t)E_t[x_{t+1}] + B(s_t)x_{t-1} + C(s_t)z_t,$$

where  $A(s_t) = B_1(s_t)^{-1}A_1(s_t)$ ,  $B(s_t) = B_1(s_t)^{-1}B_2$  and  $C(s_t) = B_1(s_t)^{-1}$ . The parameter values are chosen as follows.

|                       |                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Common Parameters     | $p_{11} = 0.85, p_{22} = 0.95, \beta = 0.99, \kappa = 0.132, \sigma = 1,$<br>$\rho = 0.7, \rho_D = \rho_S = 0.8, \rho_{MP} = 0.$ |
| Case=1: Determinate   | $\phi_\pi(1) = 0.9, \phi_\pi(2) = 1.5.$                                                                                          |
| Case=2: Indeterminate | $\phi_\pi(1) = 0.8, \phi_\pi(2) = 1.5.$                                                                                          |

The results are qualitatively similar to those of the Fisherian model. In the case of determinacy,  $\text{FCC}(1)=22$ .  $\text{DET}(1) = \rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) = 0.2839 < 1$  and  $\text{DET}(2) = \rho(\Psi_{F^* \otimes F^*}) = 0.9539 < 1$ . So the model is determinate and it is of course determinacy-admissible as  $\text{DET}(1) \times \text{DET}(2) = 0.2708 < 1$ . Since  $\text{FCC}(2) = 0.7442 < 1$ , the forward solution exists, which is given by  $x_t = \Omega^*(s_t) + \Gamma^*(s_t)z_t$ . In the case of indeterminacy,  $\text{FCC}(1)=24$ .  $\text{DET}(1) = 0.2895 < 1$  and  $\text{DET}(2) = 1.0082 > 1$ . But the model is determinacy-admissible as  $\text{DET}(1)\text{DET}(2) = 0.2919 < 1$ .

**X2figure.m**: This code computes the locus of  $\phi_\pi(1)$  and  $\phi_\pi(2)$  such that  $\rho(\Psi_{F^* \otimes F^*}) = 1$  by “fsolve.m”, which partitions the parameter space into the determinacy and indeterminacy regions.

### B.1.3 Regime-Switching Elasticity of Intertemporal Substitution

The code **X3.m** considers a New-Keynesian model with regime-switching elasticity of intertemporal substitution. The model is presented in Section 6.3 of the previous version of Cho (2016) “Characterizing Markov-Switching Rational Expectations (MSRE) models”.

$$\pi_t = \beta E_t \pi_{t+1} + \kappa y_t + z_{S,t}, \quad (26)$$

$$y_t = E_t \left[ \frac{\sigma(s_{t+1})}{\sigma(s_t)} y_{t+1} \right] - \frac{1}{\sigma(s_t)} (i_t - E_t \pi_{t+1}) + \frac{1}{\sigma(s_t)} z_{D,t}, \quad (27)$$

$$i_t = (1 - \rho) \phi_\pi \pi_t + \rho i_{t-1} + z_{MP,t}. \quad (28)$$

This example differs from the Markov-switching monetary policy model in that  $A$  depends both on  $s_t$  and  $s_{t+1}$ . This new feature can be handled by simply specifying  $A(i, j)$  for all  $i, j = 1, 2, \dots, S$ . For a numerical exercise we have  $\beta = 0.99$ ,  $\kappa = 0.132$ ,  $\phi_\pi = 1.5$ ,  $\rho_D = \rho_S = 0.95$ ,  $\rho_{MP} = 0$  and  $\rho = 0.95$ . For  $\sigma(s_t)$  we set  $\sigma(1) = 1$  and  $\sigma(2)$ . Since  $\phi_\pi > 1$ , the model would be determinate and this can be easily verified by  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*}) = 0.56$  and  $\rho(\Psi_{F^* \otimes F^*}) = 0.95$ . Of course, the model is determinacy-admissible as the product of the two metrics is less than 1.

**Remark** The impulse response function is an optional output argument of the code “fmmsre.m”. All three codes **X1.m**, **X2.m** and **X3.m** will display the impulse response functions starting at two different initial regimes.

## B.2 Codes for Replicating Cho (2021)

1. `ReplicatingFigure1.m` produces Figure 1 of Cho (2021). It applies “`fmlre.m`” and “`fmmsre.m`” for more than 120,000 times of parameter combinations in about a couple of minutes. Just run this code.
2. `Example_Corollary2_Fisher_FTPL.m` is another example for Corollary 2 using the model with regime-switching in monetary and fiscal policies in the paper. To verify Corollary 2, we need to compute all other MSV solutions. Thus, this code requires to run the code `gbmsre.m`.

## B.3 Sample Codes for Cho and Moreno (forthcoming)

Please refer to the link in the website, <https://sites.google.com/site/sc719en/research>.

## C Modified Forward Method

The original forward method of Cho and Moreno (2011) for LRE models and the forward method Cho (2016) for MSRE models yields the forward solution different from the *MOD* solution *only when* the model has a special block-recursive structure. The modification of the original forward method aims at recovering the equivalence of the forward solution and the *MOD* solution for models with a block-recursive structure or a type of models that breaks down the equivalence of the two solutions for unknowns reasons for MSRE models. Refer to Cho (2021) for detail.

The information with which expectations are formed may not contain all of the state variables for block-recursive models. Thus let the original forward method use partial information. The information can be extended to include all of the state variables regardless of the model structure. This case uses full information. Modified forward method can be summarized as follows. First, apply the original forward method. If the forward solution is the *MOD* solution, that is, if the model is determinacy-admissible, then it is done. If not, use the forward method under full information. It suffices to illustrate the forward method for MSRE models because the forward method for LRE models is just a special case. The following briefly explains the original forward method and the forward method under full information.

### C.1 Original Forward Method for MSRE models.

1. **Forward Representation of the Model (Proposition 3 of Cho (2016)):** There is a unique set of sequences  $\Omega_k(s_t)$ ,  $\Gamma_k(s_t)$  and  $F_k(s_t, s_{t+1})$  such that

$$x_t = E_t[M_k(s_t, s_{t+1}, \dots, s_{t+k})x_{t+k}] + \Omega_k(s_t)x_{t-1} + \Gamma_k(s_t)z_t, \quad (29)$$

where  $\Omega_1(s_t) = B(s_t)$ ,  $\Gamma_1(s_t) = C(s_t)$ ,  $F_1(s_t, s_{t+1}) = A(s_t, s_{t+1})$  for all  $s_t$  and  $s_{t+1}$ , and for  $k = 2, 3, \dots$ ,

$$\Omega_k(s_t) = \{I_n - E_t[A(s_t, s_{t+1})\Omega_{k-1}(s_{t+1})]\}^{-1}B(s_t), \quad (30)$$

$$\Gamma_k(s_t) = \{I_n - E_t[A(s_t, s_{t+1})\Omega_{k-1}(s_{t+1})]\}^{-1}C(s_t) + E_t[F_k(s_t, s_{t+1})\Gamma_{k-1}(s_{t+1})R(s_{t+1})], \quad (31)$$

$$F_k(s_t, s_{t+1}) = \{I_n - E_t[A(s_t, s_{t+1})\Omega_{k-1}(s_{t+1})]\}^{-1}A(s_t, s_{t+1}). \quad (32)$$

- **No-bubble Condition (NBC)** holds if  $\lim_{k \rightarrow \infty} E_t[M_k(s_t, s_{t+1}, \dots, s_{t+k})x_{t+k}] = 0_{n \times 1}$  when expectations are formed with that solution.
- **Forward Convergence Condition (FCC)**

Table 6: **Forward Convergence Conditions**

| Notations | Concepts                                                    | How to check                                                       |
|-----------|-------------------------------------------------------------|--------------------------------------------------------------------|
| FCC1      | $\Omega^*(s_t) = \lim_{k \rightarrow \infty} \Omega_k(s_t)$ | every element of $\Omega_k(s_t) - \Omega_{k-1}(s_t) \rightarrow 0$ |
| FCC2      | $\Gamma^*(s_t) = \lim_{k \rightarrow \infty} \Gamma_k(s_t)$ | $r(\Psi_{R' \otimes F^*}) < 1$                                     |

- The forward solution is:

$$x_t = \Omega^*(s_t)x_{t-1} + \Gamma^*(s_t)z_t. \quad (33)$$

- **Remark 1.** In practice,  $\Omega^*(s_t)$  always exists except for the case in which the model has no real-valued solutions – the case the FCC should not hold.
- **Remark 2.**  $F^*(s_t, s_{t+1}) = \lim_{k \rightarrow \infty} F_k(s_t, s_{t+1})$  exists whenever  $\Omega^*(s_t)$  exists.
- **Remark 3.** Existence of  $\Gamma^*(s_t)$  can be checked easily by computing  $\rho(\Psi_{R' \otimes F^*})$ . One can understand why this is true from (31). That is,  $\Gamma_k(s_t)$  explodes if  $\rho(\Psi_{R' \otimes F_K}) > 1$ .

2. **Property of the Forward Solution (Proposition 4 of Cho (2016)):** The forward solution is the unique RE solution that satisfies the NBC.
3. **Classification of the solutions by the forward method (Proposition 5 and 6 of Cho (2016)):** Suppose that the forward solution  $\Omega^*(s_t)$  exists and  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) < 1$ . Then  $\Omega^*(s_t) = \Omega^{MOD}(s_t)$ . Classify the model following Table 3 (See Cho (2021)). Done.

## C.2 Forward Method for MSRE models under Full Information.

If  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) \geq 1$ , forward one period ahead and take expectations as:

$$E_t[x_{t+1}] = E_t[k_{t+1}] + E_t[B(s_{t+1})]x_t, \quad (34a)$$

which must be true under rational expectations where  $k_t = E_t[A(s_t, s_{t+1})x_{t+1}]$ .  $E_t[B(s_{t+1})]$  at each regime  $s_t$  can be easily computed by  $\sum_j^S P(i, j)B(s_{t+1} = j)$  at each  $s(t) = i = 1, \dots, S$ . Then the model is transformed as follows.

$$x_t = k_t + B(s_t)x_{t-1} \quad (35a)$$

$$k_t = E_t[A(s_t, s_{t+1})x_{t+1}] + H(E_t[x_{t+1}] - E_t[k_{t+1}] - E_t[B(s_{t+1})]x_t), \quad (35b)$$

where  $H$  is an  $n \times n$  matrix in which every single element is arbitrary but non-zero. Applying the expectational relation of the whole model is innocuous because it must hold regardless of block-recursiveness of the model. By doing this, the model is no-longer block-recursive and has no autonomous block. Now we write this into the original form of the model in the following way. Let  $y_t = [x_t' k_t']'$  be a  $2n \times 1$  vector. Notice that  $E_t[B(s_{t+1})]$  is a function of  $s_t$ . Collecting the coefficient matrices yields:

$$\begin{bmatrix} I_n & -I_n \\ HE_t[B(s_{t+1})] & I_n \end{bmatrix} y_t = E_t \left[ \begin{bmatrix} 0_{n \times n} & 0_{n \times n} \\ A(s_t, s_{t+1}) + H & -H \end{bmatrix} y_{t+1} \right] + \begin{bmatrix} B(s_t) & 0_{n \times n} \\ 0_{n \times n} & 0_{n \times n} \end{bmatrix} y_{t-1},$$

Finally, by multiplying the inverse of the coefficient matrix of  $y_t$ , we have the following form of the model:

$$y_t = E_t[A^y(s_t, s_{t+1})y_{t+1}] + B^y(s_t)y_{t-1}. \quad (36)$$

Forward method under full information is to apply the forward method to (36) and obtain the solution for  $y_t$ .

$$y_t = (\Omega^y(s_t))^* y_{t-1}. \quad (37)$$

The solution  $(\Omega^y(s_t))^*$  is  $2n \times 2n$  and since  $x_t$  is the first  $n \times 1$  subvector of  $y_t$ , the first  $n \times n$  component of  $(\Omega^y(s_t))^*$  is the forward solution of the original model under the modified forward method.

### C.3 Existence of the Forward Solution

Both the original model (12) and the adjusted model (36) has the same form. Therefore, we can examine the existence condition for the forward solution using the same formula as (30) and (32). Under the modified forward method,  $\Omega_k(s_t)$  can be interpreted as  $\Omega_k^y(s_t)$  in (37). The condition for the existence of the forward solution can be understood by differentiating

and vectoring (30) such that:

$$\begin{bmatrix} \text{vec}(d\Omega_k(1)) \\ \dots \\ \text{vec}(d\Omega_k(S)) \end{bmatrix} = \left[ \Psi_{\Omega'_{k-1} \otimes F_{k-1}} \right] \begin{bmatrix} \text{vec}(d\Omega_{k-1}(1)) \\ \dots \\ \text{vec}(d\Omega_{k-1}(S)) \end{bmatrix}. \quad (38)$$

Proposition 4 of Cho (2021) formally states the convergence condition for  $\Omega_k$ . There are two possibilities:

1.  $\rho(\Psi_{\Omega'_{k-1} \otimes F_{k-1}}) < 1$  for all  $k > K \gg 1$ .
2.  $\rho(\Psi_{\Omega'_{k-1} \otimes F_{k-1}}) \geq 1$  for some  $k > 1$  and  $u'_k \text{vec}(d\Omega_{k-1}) = 0_{n^2 S \times 1}$  for every eigenvector  $u_k$  associated with an unstable root of  $\Psi_{\Omega'_{k-1} \otimes F_{k-1}}$ .

Under the original forward method, Proposition 4 states that the equivalence of the forward solution and the *MOD* solution may break down only in the second case. In that case, even if  $\Psi_{\Omega'_{k-1} \otimes F_{k-1}}$  contains a root larger than unity, it does not affect  $\Omega_k$ , thus the forward solution can still exist. The forward method under full information is to adjust the model such that Case 2 of Proposition does not arise in the class of determinacy-admissible models.<sup>2</sup> Then Case 1 implies that in the MSRE framework, the forward solution exists for a broader class of models including determinacy-inadmissible models because,  $\rho(\Psi_{\Omega^{*'} \otimes F^*}) < 1$  can be consistent with  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) \geq 1$ . That is, if  $\rho(\bar{\Psi}_{\Omega^* \otimes \Omega^*})\rho(\Psi_{F^* \otimes F^*}) < 1$ , then  $\rho(\Psi_{\Omega^{*'} \otimes F^*}) < 1$ , but the converse is not true in general. An extensive experiment so far has never found a single case in which the forward solution is not the *MOD* solution in atheoretical and economic examples. Nevertheless, the equivalence to a model with a real-valued *MOD* solution is an open question to be explored in the future.

---

<sup>2</sup>When a model has completely decoupled equations, Case 2 still exists even under the forward method under full information. The example in Section 4 when  $c = 0$  is such a case. However, recall that in that case, the solution with the smallest generalized eigenvalues does not exist, thus the model is determinacy-inadmissible. Moreover, the forward solution coincides with the *MOD* solution.
